Colloque IPhT Batz-sur-Mer 17/10/2008

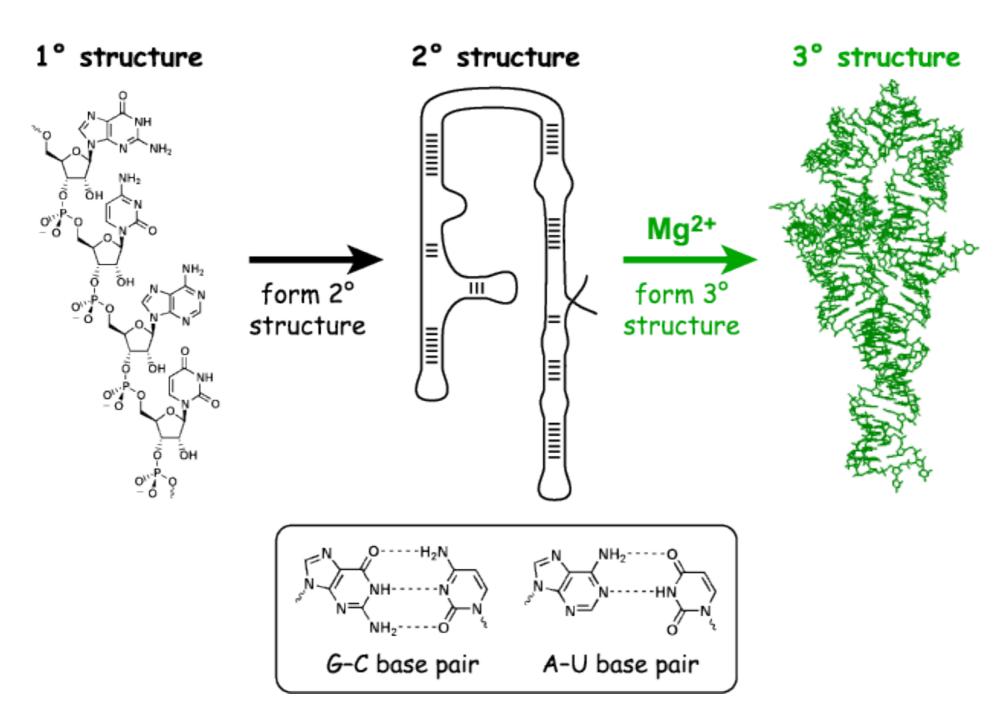

# Why trees?

- Population dynamics & genealogy
- Biology, Evolution
- Growth processes
- Branched polymers
- Statistical mechanics
- Spanning trees, random matrices
- Quantum gravity (2d & 3d)
- Combinatorics
- Computer science, data bases, XML, etc.
- Optimisation problems
- Social sciences, economics
- etc.

# First problem: RNA folding & random splitting trees

RNA primary, secondary and tertiary structure

# Problem: find the secondary (and the tertiary) structure from the base sequence

GCCUUAAUGCACAUGGGCAAGCCCACGUAGCUAGUCGCGCGACACCAGUCCCAAAUAAUGUUCACCCAACUCGCCUGACCGUCCCGCAGUA GCUAUACUACCGACUCCUACGCGGUUGAAACUAGACUUUUCUAGCGAGCUGUCAUAGGUAUGGUGCACUGUCUUUAAUUUUGUAUUGGGCC AGGCACGAAAGGCUUGGAAGUAAGGCCCCGCUUGACCCGAGAGGUGACAAUAGCGGCCAGGUGUAACGAUACGCGGGUGGCACGUACCCCA AACAAUUAAUCACACUGCCCGGGCUCACAUUAAUCAUGCCAUUCGUUGCCGAUCCGACCCAUAUAGGAUGUGUAUGCCUCAUUCCCGGUCG GGGCGGCGACUGUUAACGCAUGAGAACUGAUUAGAUCUCGUGGUAGUGCUUGUCAAAUAGAAUGAGGCCAUUCCACAGACAUAGCGUUUCC CAUGAGCUAGGGGUCCCAUGUCCAGGUCCCCUAAAUAAAAGAGUC

- I. "kissing hairpins" & interlaced strands are rare (unfavored by kinematics & topology)
- 2. RNA can (to some extent) be considered as a **planar tree**

Random bond RNA model (R. Bundshuh and T. Hwa)

Question: Which features are sequence dependent (biological functions) and which are generic?

Long chain with random sequence of bases

Allows numerical and analytical studies (in particular at IPhT...)

Exhibit a freezing transition at a finite temperature Tg

High temperature molten phase (many equivalent microstates - generic tree with fractal dimension 2)

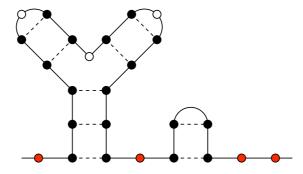

Low temperature frozen state (the system is frozen in one of the minimal energy configurations, like in a glass or a spin-glass)

#### The (planar) random bond RNA folding model

I) Start from a strand made of L random bases  $b_1 b_2 b_3 \cdots b_L$ 

2) Fold it in a planar way (neither knots nor pseudo-knots)

3) Assign to each configuration an energy sum of an energy for each bond

$$\mathcal{E} = \sum_{\text{pairs } (ij)} e(i,j)$$

4) Take the bond energies to be independent Gaussian quenched random variables

$$\overline{e(i,j)e_{(k,l)}} = \sigma \,\delta_{ik}\delta_{jl}$$

... instead of a function of the random bases

$$e(b_i, b_j)$$

5) And find the lowest energy configuration (ground state at zero temperature)

.....This is a difficult problem: infinite range forces & topological frustration

A simple step-by-step strategy to find a (hopefully not too bad) approximation of the ground state

A simple step-by-step strategy to find a (hopefully not too bad) approximation of the ground state

Chose as first pairing the pairing with lowest energy

A simple step-by-step strategy to find a (hopefully not too bad) approximation of the ground state

Chose as first pairing the pairing with lowest energy

Chose as second pairing the planar pairing left with the lowest energy

A simple step-by-step strategy to find a (hopefully not too bad) approximation of the ground state

Chose as first pairing the pairing with lowest energy

Chose as second pairing the planar pairing left with the lowest energy

Iterate until we cannot add any pairing

A simple step-by-step strategy to find a (hopefully not too bad) approximation of the ground state

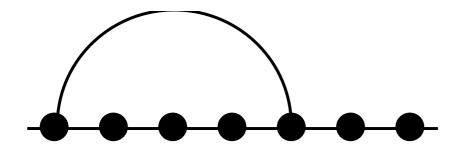

Chose as first pairing the pairing with lowest energy

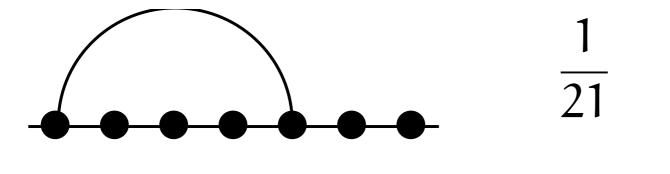

Chose as second pairing the planar pairing left with the lowest energy

Iterate until we cannot add any pairing

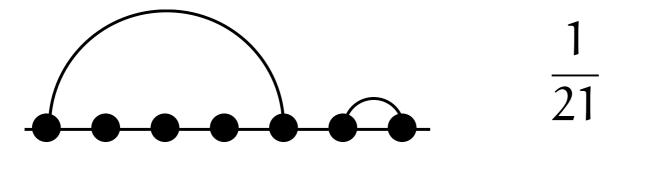

Since the pair energies are independent, this amounts to build an arch system by successive random deposition of arches

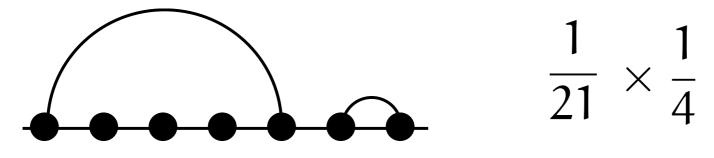

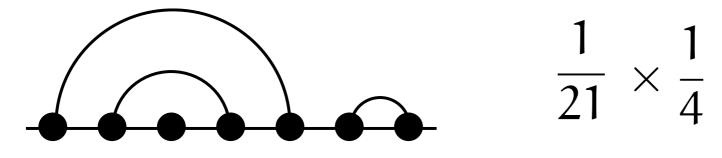

$$\frac{1}{21}$$

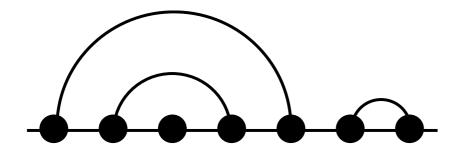

$$\frac{1}{21}$$

$$\frac{1}{21} \times \frac{1}{4}$$

$$\frac{1}{21} \times \frac{1}{4}$$

$$\frac{1}{21} \times \frac{1}{4} \times \frac{1}{3}$$

$$\frac{1}{21} \times \frac{1}{4} \times \frac{1}{3}$$

At each step, choose a new arch with uniform probability among all possible arches.

A final configuration is constructed via several deposition processes

Total probability

$$\frac{1}{21} \times \frac{1}{4} \times \frac{1}{3}$$

At each step, choose a new arch with uniform probability among all possible arches.

A final configuration is constructed via several deposition processes

Total probability 
$$\frac{1}{84} + \frac{1}{630} + \frac{1}{210} + \frac{1}{252} + 2\frac{1}{126} = \frac{4}{105}$$

$$\frac{1}{21} \times \frac{1}{4} \times \frac{1}{3}$$

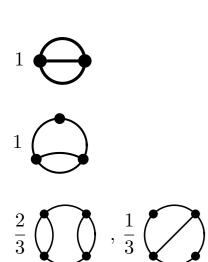

At each step, choose a new arch with uniform probability among all possible arches.

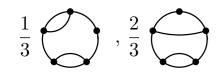

A final configuration is constructed via several deposition processes

Total probability 
$$\frac{1}{84} + \frac{1}{630} + \frac{1}{210} + \frac{1}{252} + 2\frac{1}{126} = \frac{4}{105}$$

Relation to fragmentation models?

Not a model for real-time RNA folding

We generate an ensemble of configurations with non-trivial weights (different from those obtained by local processes, no combinatorics...)

$$\frac{1}{3} \bigcirc , \frac{2}{15} \bigcirc , \frac{1}{5} \bigcirc , \frac{2}{15} \bigcirc , \frac{1}{5} \bigcirc , \frac{2}{15} \bigcirc , \frac{1}{5} \bigcirc$$

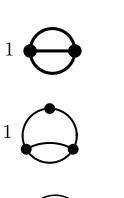

$$\frac{8}{45} \bigcirc , \frac{4}{15} \bigcirc , \frac{1}{15} \bigcirc , \frac{1}{5} \bigcirc , \frac{8}{45} \bigcirc , \frac{1}{9} \bigcirc$$

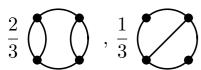

$$\frac{2}{105} \bigcirc , \frac{8}{45} \bigcirc , \frac{8}{63} \bigcirc , \frac{17}{315} \bigcirc , \frac{4}{45} \bigcirc , \frac{4}{63} \bigcirc , \frac{4}{105} \bigcirc , \frac{8}{315} \bigcirc , \frac{4}{105} \bigcirc , \frac{8}{315} \bigcirc$$

$$\frac{2}{21} \bigcirc , \frac{2}{21} \bigcirc , \frac{16}{315} \bigcirc , \frac{4}{63} \bigcirc , \frac{4}{105} \bigcirc$$

$$\frac{5}{63} \bigcirc , \frac{7}{90} \bigcirc , \frac{2}{63} \bigcirc , \frac{1}{105} \bigcirc , \frac{4}{63} \bigcirc , \frac{7}{90} \bigcirc , \frac{1}{21} \bigcirc , \frac{31}{315} \bigcirc , \frac{1}{21} \bigcirc , \frac{19}{315} \bigcirc$$

$$\frac{2}{63} \bigcirc , \frac{19}{315} \bigcirc , \frac{4}{105} \bigcirc , \frac{2}{63} \bigcirc , \frac{13}{630} \bigcirc , \frac{11}{420} \bigcirc , \frac{13}{630} \bigcirc , \frac{11}{420} \bigcirc , \frac{13}{630} \bigcirc$$

$$\frac{1}{3}$$
 ,  $\frac{2}{3}$ 

We generate an ensemble of configurations with non-trivial weights (different from those obtained by local processes, no combinatorics...)

$$\frac{8}{45}$$

## Tools: recursion relations for probabilities and height

heights = number of arches above a point (Dyck & Motzkin paths)

#### Many explicit results

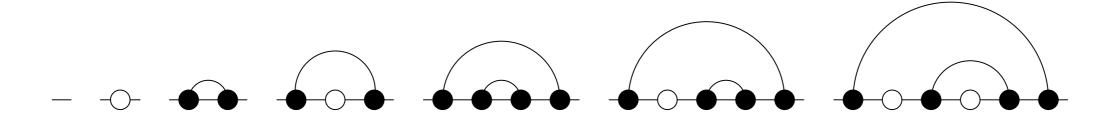

Hausdorff dimension

$$\zeta^2 + 3\zeta = 2$$
,  $\zeta = \frac{\sqrt{17} - 3}{2} = 0.561...$ ,  $d_F = \frac{1}{\zeta} = 1.78... < 2$ 

Scaling functions in term of hypergeometric functions

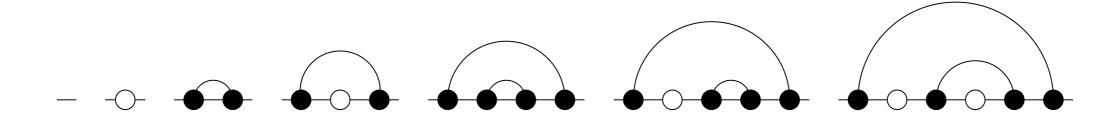

## This model is equivalent to a tree growth model!

Random deposition point model: successive deposition of points on intervals & create an arch whenever it is possible

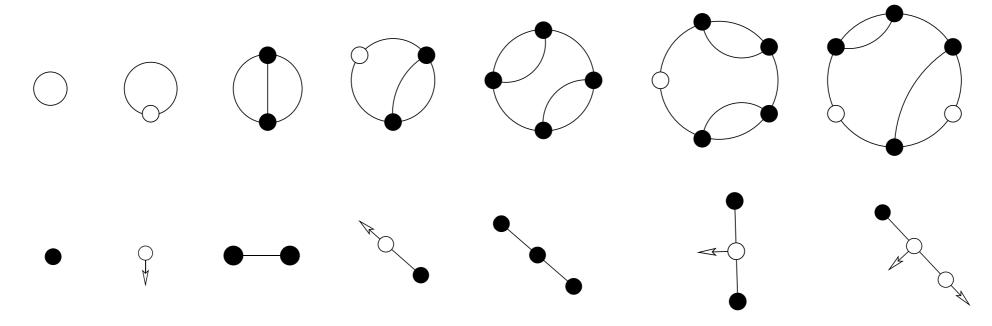

# This model is equivalent to a tree growth model!

Random deposition point model: successive deposition of points on intervals & create an arch whenever it is possible

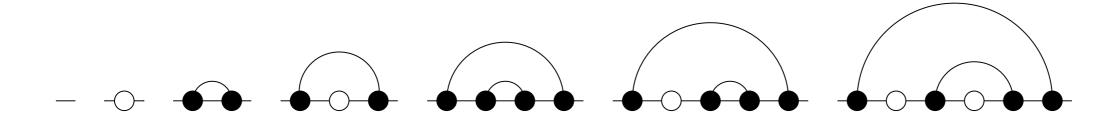

Closing + duality gives a decorated tree growth model

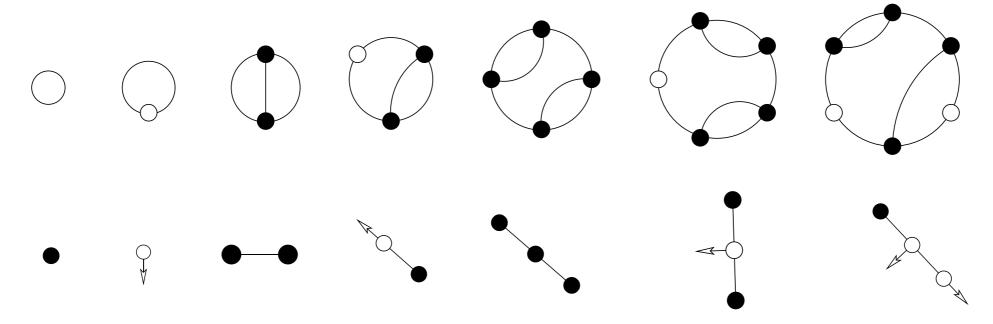

# This model is equivalent to a tree growth model!

Random deposition point model: successive deposition of points on intervals & create an arch whenever it is possible

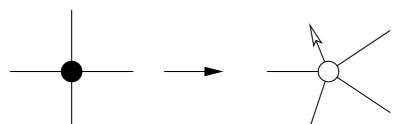

Closing + duality gives a decorated tree growth model

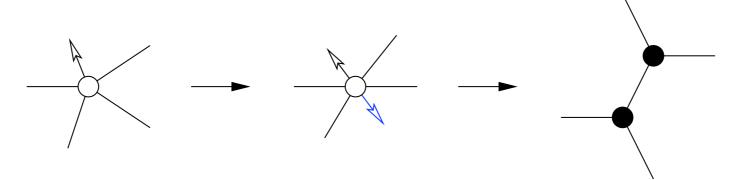

arch/tree growth at time t = arch deposition for size n=t!

#### 2 steps growth process:

- add a leaf to a vertex: 1 black → 1 white

- add a second leaf = "splitting" 1 white → 2 black

 $k \text{ white } \rightarrow (k_1, k_2) \text{ black } k_1 + k_2 = k + 2$ 

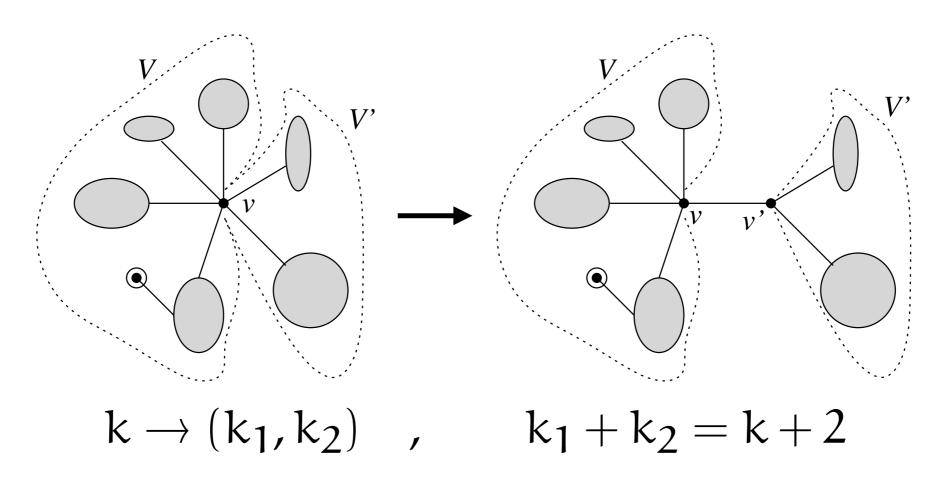

NB: attachment is just a special case

$$k_1 = 1$$
,  $k_2 = k + 1$ 

Proof of the equivalence deposition = growth by splitting Use the recursion relation for probabilities for both models

# Simpler but more general model: growth of planar trees by splitting

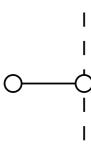

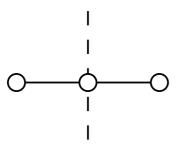

Relative probability for specific splitting of a vertex  $w_{k_1,k_2}$ 

Relative probability for splitting of a vertex

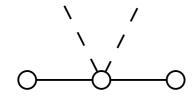

$$w_k = \frac{k}{2} \sum_{k_1 + k_2 = k+2} w_{k_1, k_2}$$

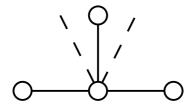

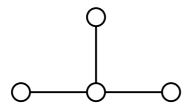

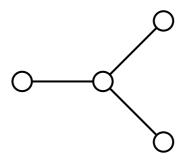

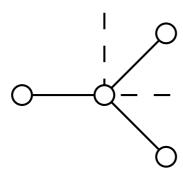

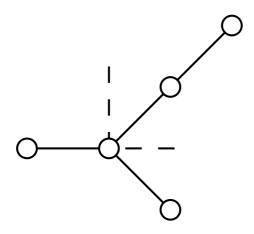

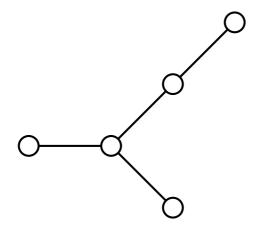

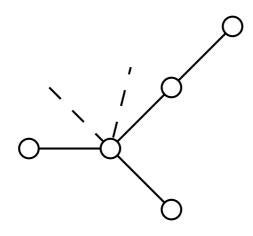

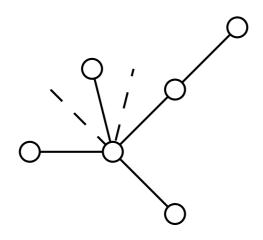

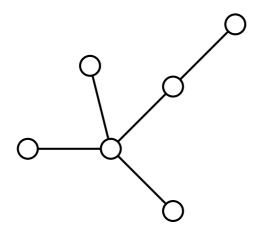

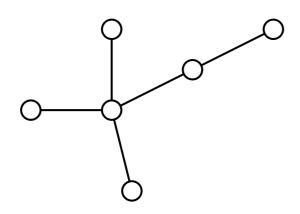

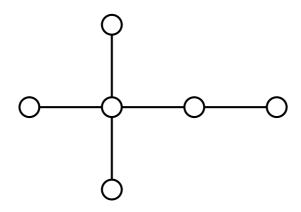

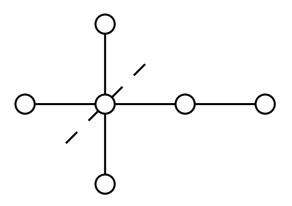

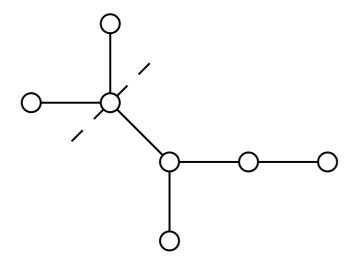

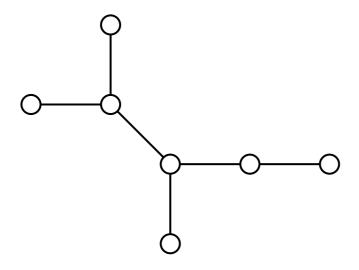

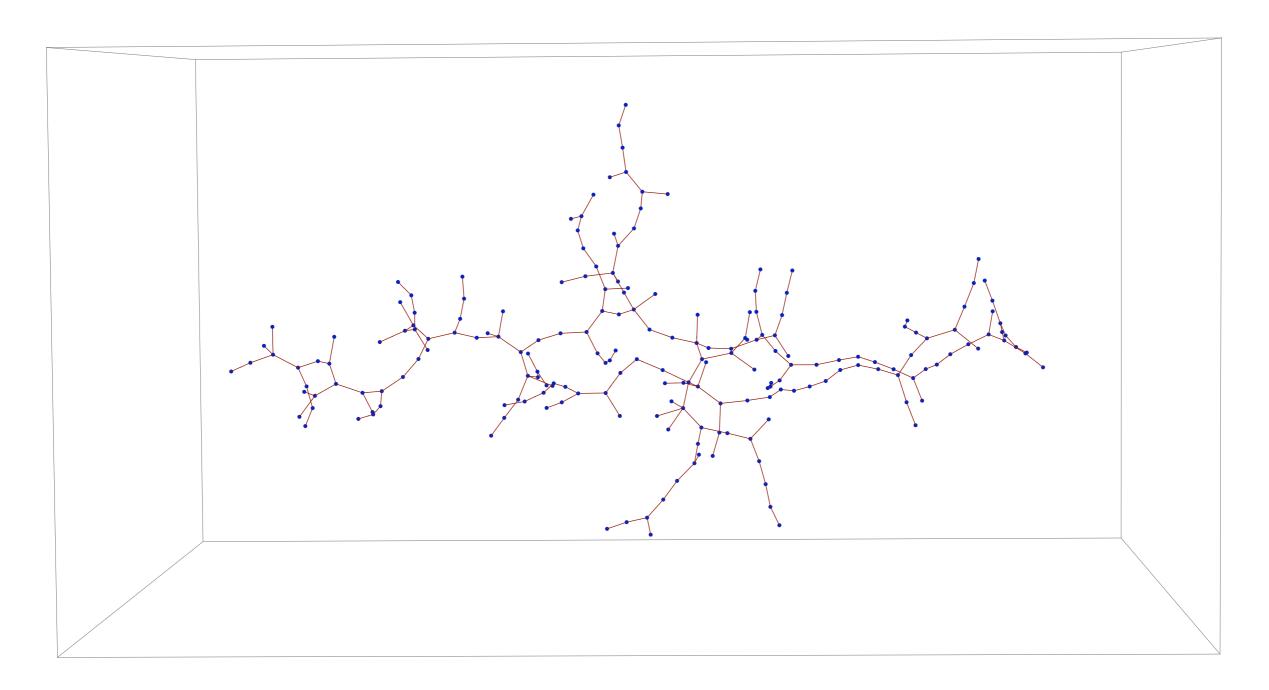

- What kind of trees do we get?
- Like scale-free networks? (vertex with large coordination, infinite Hausdorff dimension)
- Or like generic trees (finite coordination, finite Hausdorff dimension)
- Universal properties?
- Do the Hausdorff dimension depend on the details of the transition rates matrix

#### Simple example:

Maximal coordination 3

Uniform transition rates

$$w_{1,2} = w_{2,1} = \frac{w_1}{2}$$
 $w_{1,3} = w_{2,2} = w_{3,1} = \frac{w_2}{3}$ 
 $w_{3,2} = w_{2,3} = \frac{w_3}{2}$ 

Linear k-dependence

$$w_k = ak + b$$

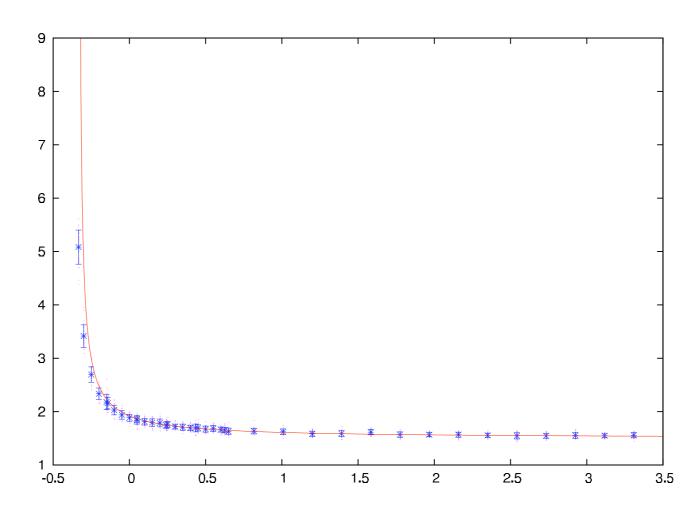

General approach: recursions for correlations

$$x = a/b$$

$$d_{H} = \frac{3(\sqrt{100x^{2} + 84x + 17} + 2x + 1)}{8(3x + 1)}$$

#### Hausdorff dimension varies continuously

$$1 < d_H < \infty$$

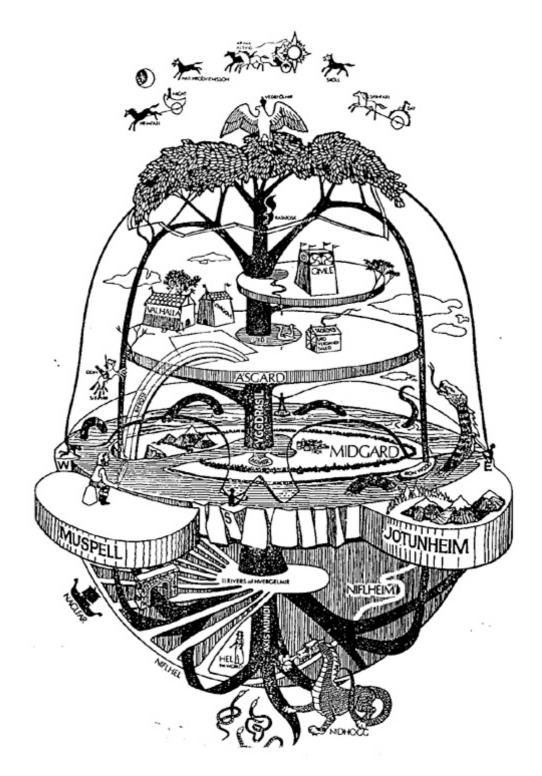

#### Conclusion: the world as a tree?

#### Conclusion: the world as a tree?

# Thanks to the organizers!
